Epidemiology and Eco-friendly Management of Chilli Fruit Rot Disease Gottapu Darwin,2013 The present investigation was carried out in Department of Plant Pathology, Agricultural College, Bapatla, ANGRAU, Hyderabad, Andhra Pradesh, India. The main objective of this work is by understanding the disease development and reduce the environmental hazards. This book brings together a holistic picture of the various concepts of inoculation methods, inoculum concentration in relation to disease development; effect of environmental factors on chilli fruit rot development; and managing the disease in an eco-friendly manner.

Anthracnose of Chilli Jameel Akhtar,Raj Kiran,Pardeep Kumar,Meena Shekhar,2018 Chilli (Capsicum annuum L.) is one of the most economically important vegetable crops in the world. Among different biotic constraints, anthracnose disease is the major limiting factor affecting yield and production of chilli crop. Different symptoms associated with disease are fruit rot, leaf spots, dieback on stem, seedling blight, or damping off. Many species of genus Colletotrichum are found associated

with the disease worldwide. In India, primarily three important species, namely, *Colletotrichum truncatum*, *C. acutatum*, and *C. gleosporoides*, are responsible for the chilli anthracnose. Accurate identification of pathogen is needed for choosing the proper management strategy for controlling this disease. Both conventional and molecular methods are adapted along with different management strategies, recommended for this disease namely cultural, chemical, and other eco-friendly methods.

Benckiser,Krishnamurthy Kumar,Anton Hartmann,Bernd Honermeier,2019-04-03 Nature's high biomass productivity is based on biological N₂ fixation (BNF) and biodiversity (Benckiser, 1997; Benckiser and Schnell, 2007). Although N₂ makes up almost 80% of the atmosphere's volume living organisms need it in only small quantities, presumably due to the paucity of natural ways of transforming this recalcitrant dinitrogen into reactive compounds. N shortage is commonly the most important limiting factor in crop production. The synthesis of ammonium from nitrogen and hydrogen, the Haber-Bosch (H-B) process, invented more than 100 years ago, became the holy grail of synthetic inorganic chemistry and removed the most ubiquitous limit on crop yields. H-B opened the way for the development and adoption of high-yielding cultivars, for monoculturing by organic and precision farming. With N over fertilization and pesticide application monoculturing farmers could approach Nature's high biomass productivity by causing side effects the scientific world is investigating. This eBook presents the complexity the scientific world is facing in understanding the soil-microbe-plant-animal cooperation, the millions of taxonomically, phylogenetically, and metabolically diverse above-below-ground species, involved in shaping the ever-changing biogeochemical process patterns being of great significance for food production networks and yield stability. Because ecosystem management and agricultural praxis are still largely conducted in isolation, the aim of this Frontiers' eBook is to gather and interconnect plant-microbe-insect interaction research of various disciplines, studied with a broad spectrum of modern physical-chemical, biochemical, and molecular biological, agronomical techniques. The goal of this Research Topic was to gain a better understanding of microbe-plant-insect compositions, functioning, interactions, health, fitness, and productivity.

Anthracnose Disease of Mango Frederick Kankam,Stephen Larbi-Koranteng,Joseph Adomako,Joseph Kwodaga,Isaac

Boatey Akpatsu, Yaw Danso, Elias Nortaa Kunedeb Sowley, 2019 Mango is one of the frequently cultivated seasonal fruit crops in several tropical and subtropical regions. It is consumed as whole fruits apart from serving as raw materials for most industries that are into mineral production. Mango production is, however, constrained by diseases, pests, and poor post-harvest handling of fruits. Anthracnose disease, caused by *Colletotrichum gloeosporioides* Penz and Sacc, is one of the most important yields limiting constraint in mango production across the globe. The disease occurs in both the field and post-harvesting. In the field, it affects aboveground parts, such as the stem, branches, leaves, flowers, and fruits. Anthracnose disease reduces the shelf life and marketability of mango fruit. In Ghana, anthracnose disease is responsible for about 30% yield/fruit loss. Most farmers do not control it, although some have resorted to the application of various fungicides not registered for mango anthracnose disease management in Ghana. This chapter will highlight on the importance of the disease on the mango industry in Ghana, control strategies currently employed thereby reducing the over-reliance on chemical control option and propose ways to minimize the effect of the disease in the country.

An Investigation Into the Epidemiology and Control of Anthracnose (Colletotrichum Truncatum) of Lentil in Manitoba
Richard J. Gibson, 2012

An Investigation Into the Epidemiology and Control of Anthracnose (*Colletotrichum Truncatum*) of Lentil in Manitoba [microform] Richard J. Gibson, 1994 Repeated foliar application of chlorothalonil significantly increased lentil (*Lens culinaris*) seed yield in field plots infested with anthracnose caused by *Colletotrichum truncatum*. Two to four fold increases over the yields of non-treated plots occurred when conditions for disease development were favourable. Propiconazole significantly increased seed yield at an irrigated test site at the University of Manitoba Campus Farm but did not significantly improve seed yield at other sites, probably due to dry conditions. Levels of infestation in harvested seed were generally low, ranging from 2.25% in seed from 16 commercial lentil fields, to below 1.42% from untreated plots and less than 0.25% from plots sprayed with chlorothalonil. No evidence of seed to seeding transmission was obtained when seed lots with 6.4%, 3.4% and 2.3% infected seed were sown in isolated plots at the Campus Farm. Propiconazole reduced disease severity on lentil when applied up to 48 hours after plants were inoculated with *C. truncatum* in the greenhouse. Chlorothalonil did not reduce disease severity when applied to plants 24 or 48 hours after inoculation. In growth cabinet studies, disease severity on inoculated lentil plants increased with increasing temperature and length of leaf wetness periods. Symptomless infection of lentil and faba bean was demonstrated in field and greenhouse studies. The ability of *C. truncatum* to overwinter on lentil stubble for up to two years in a commercial field was determined using a bioassay. In a three-year field study, lentil cultivars and breeding lines were ranked for disease severity from lowest to highest as follows; Indianhead, Laird, Laird-cross La x 17310-8, Eston, followed by the landraces French Green, Chilean and Spanish Brown. Greenhouse studies showed that lentil, faba bean (*Vicia faba*), field pea (*Pisum sativum*), flat pea (*Lathyrus* sp.) and vetch (*Vicia sativa*)

were susceptible to *C. truncatum* from lentil. Several cultivars of soybean (*Glycine max*) and field bean (*Phaseolus vulgaris*) were resistant to *C. truncatum* from lentil.
